## About eDNA Expeditions

UNESCO's eDNA Expeditions is a global, citizen science initiative that is conducted with the intention to measure marine biodiversity and predict the impact climate change on marine community composition across UNESCO World Heritage marine sites.

eDNA is a cost effective and minimally invasive method to measure biodiversity in any given area. Marine species continuously shed DNA into the water around them in the form of waste, mucus, or cells. By extracting this DNA from water samples, and subsequently multiplying and sequencing specific regions within these DNA strands, a wide variety of species can be detected without removing any organisms from their environment. The regions in the DNA targeted for sequencing are selected depending on the scope of the study: while some markers are suitable to obtain a broad overview of biodiversity across many groups of species, other markers are particularly suited to get high resolution insight for a more specific taxonomic group such as fish. The UNESCO eDNA Expeditions initiative combines a number of markers tailored for marine vertebrates (fish, mammals, and turtles). A general marker was added to also allow detection of species from other groups such as invertebrates, which can give a broader insight in the marine species diversity in a given area.

Between September 2022 and May 2023, UNESCO organized eDNA sampling campaigns in 21 marine World Heritage sites across 17 countries around the world. At every World Heritage site, about 20 samples were collected from different habitats. Over 250 young people participated in the local sampling expeditions. They were guided by local experts and park management staff, using protocols and eDNA sampling equipment provided by UNESCO.

Biodiversity inventories generated from the samples are being combined with existing species distribution data from public biodiversity databases such as the Ocean Biodiversity Information System (OBIS) in view of obtaining a comprehensive overview of marine life across marine World Heritage sites. Through the use of climate scenarios and species distribution models, an estimate will be made of the impact of climate change, in particular rising temperatures, on local biodiversity and its potential future distribution patterns.

More information about the initiative and a press kit are available on the UNESCO website: <https://www.unesco.org/en/edna-expeditions>.

## Results

### Sampling and sample processing

eDNA sampling was conducted in Brazilian Atlantic Islands: Fernando de Noronha and Atol das Rocas Reserves in November 2022. A total of 12 samples were collected at 3 locations in the park covering different habitats: baia\_dos\_delfines, cagarras, and sueste (Figure 1). Up to 1,500 mL of seawater was filtered through filter cartridges containing a filter with a 0.8  $\mu$ m pore size. After sampling, the filter cartridges were flushed with preservation liquid and shipped to UNESCO. DNA from the samples was extracted and amplified, and subsequently sent to the sequencing facility at KU Leuven in Belgium, a specialized university eDNA lab contracted by UNESCO for this work. PCR amplification was done using five primer pairs selected to capture as much biodiversity as possible in the target groups of the study: fish, mammals, and turtles.

Figure 1: Map of the sampling locations.

### DNA sequencing

Sequencing of the DNA from 12 samples resulted in over 18 million sequence reads, from which we collected 34,170 unique sequences or ASVs (Tables 1 and 2).

reads	asvs
18614516	34170

### Species identification

The marker sequences obtained from sequencing were matched with sequence reference databases built using public data available from the National Center for Biotechnology Information (NCBI). This resulted in the

identification of 322 species, including 96 fish species, 4 mammalian species, and 1 turtle species (Table 3). Species from other groups, such as algae, sponges, crustaceans, cnidarians, and molluscs, were also detected (Figures 2 and 3). This number of species detected represents about 22% of the 1,004 species known from Brazilian Atlantic Islands: Fernando de Noronha and Atol das Rocas Reserves in the OBIS database. Of the 322 species detected, 198 are not among the species previously reported from Brazilian Atlantic Islands: Fernando de Noronha and Atol das Rocas Reserves to the UNESCO OBIS database. 4 of the detected species are listed as threatened on the IUCN Red List (Table 4). A full list of species is added at the end of this report.

group	eDNA species	total species	fraction
fish	96	446	0.22
mammals	4	6	0.67
turtles	1	4	0.25
