

# UNESCO environmental DNA (eDNA) Expeditions in marine World Heritage sites

## Biodiversity survey for Lagoons of New Caledonia: Reef Diversity and Associated Ecosystems

Interim Results Based on 50% of Samples Analyzed  
Not for public distribution

UNESCO's eDNA Expeditions is a global, citizen science initiative that is conducted with the intention to measure marine biodiversity and predict the impact climate change on marine community composition across UNESCO World Heritage marine sites.

eDNA is a cost effective and minimally invasive method to measure biodiversity in any given area. Marine species continuously shed DNA into the water around them in the form of waste, mucus, or cells. By collecting this DNA from water samples, and subsequently amplifying and sequencing specific regions within these DNA strands, experts can detect a wide variety of species without removing any organisms from their environment. The amplified regions are selected depending on the scope of the study: while some markers are suitable to obtain a broad overview of biodiversity across many groups of species, other markers are particularly suited to get high resolution insight for a more specific taxonomic group. The UNESCO eDNA Expeditions initiative combines a number of markers tailored for marine vertebrates (fish, mammals, and turtles). A general marker was added to allow to detect also species from other groups such as invertebrates which can give a broader insight in the marine species diversity in a given area.

Between September 2022 and May 2023, UNESCO organized eDNA sampling campaigns in 21 marine World Heritage sites across 17 countries around the world. At every World Heritage site, about 20 samples were collected from different habitats. Over 250 young people participated in the local sampling expeditions. They were guided by local experts and park management staff, using protocols and eDNA sampling equipment provided by UNESCO.

Biodiversity inventories generated from the samples are being combined with existing species distribution data from public biodiversity databases such as the Ocean Biodiversity Information System (OBIS) in view of obtaining a comprehensive overview of marine life across marine World Heritage sites. Through the use of climate scenarios and species distribution models, an estimate will be made of the impact of climate change, in particular rising temperatures, on local biodiversity and its potential future distribution patterns.

More information about the initiative is available on the UNESCO website: <https://www.unesco.org/en/edna-expeditions>.

## Results

### Sampling and sample processing

eDNA sampling was conducted in Lagoons of New Caledonia: Reef Diversity and Associated Ecosystems in March and April 2023. A total of 20 samples were collected at 5 locations in the park: Entrecasteaux, Grand Lagoon Nord, Kouare, Poe zco, and Pouebo (Figure 1). Up to 1800 mL of seawater was filtered through filter cartridges with a 0.8  $\mu\text{m}$  pore size. After sampling, the filter cartridges were flushed with preservation liquid and shipped to UNESCO. From the 20 samples, 9 have now (December 2023) been processed. A second batch of samples will be processed in January 2024. DNA from these samples was extracted and amplified, and then sent to the sequencing facility at KU Leuven in Belgium, a specialized university eDNA lab contracted by UNESCO for this work. PCR amplification was done using five primer pairs selected to capture as much biodiversity as possible in the target groups of the study: fish, mammals, and turtles. The results in this preliminary report are based on a first batch of 9 samples that were analyzed covering all locations that were sampled in the World Heritage site.

Figure 1: Map of the sampling locations.

### DNA sequencing

Sequencing of the DNA from 9 samples resulted in over 18 million sequence reads (Table 2), from which we collected 32368 unique sequences or ASVs. By matching those sequences with reference sequences in public databases, we were able to detect 647 species. Most of these species are vertebrates, but also species from

other groups were detected, including algae, molluscs, jellyfish, starfish, and crustaceans (Figure 2). Of the 647 species detected, 232 are not among the 8458 species previously reported from Lagoons of New Caledonia: Reef Diversity and Associated Ecosystems to the UNESCO OBIS database.

reads	asvs
18041783	32368

Pouebo	EE0278	1800	1457876	10719	229

Table 2: Reads, ASVs, and species by sample.

## Species identification

The marker sequences obtained from sequencing were matched with sequence reference databases built using public data available from the National Center for Biotechnology Information (NCBI). This resulted in the identification of 647 species, of which 342 fish species, 0 mammalian species, and 0 turtle species (Table 3). This represents about NA% of the species known from Lagoons of New Caledonia: Reef Diversity and Associated Ecosystems in the OBIS database. 10 of the detected species are listed as threatened on the IUCN Red List (Table 4). A full list of species is added at the end of this report.

group	eDNA species	total species	fraction
fish	342	2456	0.14
mammals		23	
turtles		5	

Table 3: Number of species in the three target groups, from the OBIS database and from eDNA sampling.

category	eDNA species	total species	fraction
CR		6	
EN	2	26	0.08
VU	8	101	0.08

Table 4: Number of species by IUCN Red List category, from the OBIS database and from eDNA sampling.
